

Notes 4

How to install and remove software using the APT command?

To install software, you use "sudo apt install package-name". If you want to completely remove the program and its configuration files, you can use "sudo apt purge package-name". You can also run "sudo apt update" to refresh the package list.

How to create a shell script step by step including screenshots and how to run it. Try to be as detailed as possible.

To create a shell script step by step, first open a text editor. Then type the script.

A screenshot of a text editor window with a dark theme. The title bar shows "bin bash echo Hello world" and "Draft". The editor contains three lines of code: line 1 is "#!/bin/bash", line 2 is "echo \"Hello world!\"", and line 3 is a cursor at the start of a new line.

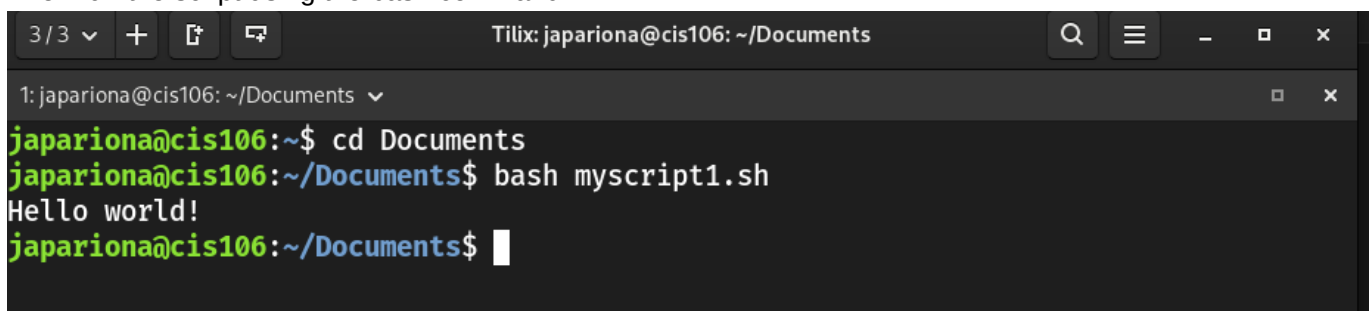

```
1 #!/bin/bash
2 echo "Hello world!"
3 |
```

The first line, #!/bin/bash, tells Linux to run the script using bash. The second line prints the message to the screen.

Next, save the file with a .sh extension, such as:

After saving it, open the terminal and go to the folder where the script was saved by using the cd command. Then run the script using the bash command:

A screenshot of a terminal window. The title bar shows "Tilix: japariona@cis106: ~/Documents". The terminal shows the user navigating to the Documents directory and running the script "myscript1.sh", which outputs "Hello world!".

```
1: japariona@cis106: ~/Documents
japariona@cis106:~$ cd Documents
japariona@cis106:~/Documents$ bash myscript1.sh
Hello world!
japariona@cis106:~/Documents$
```

This tells the system to execute the script using Bash. When the script runs, it will display the message written in the script.
